Unit #4

MIS5214

Case Study 1 and Cryptography

Agenda

- Team Project It is not too early to get started...
- Case Study 1
- Cryptography terminology
- Symmetric Key Cryptography
 - Symmetric stream cryptography
 - Symmetric block cryptography
- Key sharing problem
- Public Key Cryptography
 - Diffie-Hellman algorithm: symmetric key generation through asynchronous cryptography
 - RSA algorithm
- Hybrid-Cryptography
 - Perfect Forward Secrecy
- Where do cryptographic controls go in the FedRAMP System Security Plan
- Brief review: Hashing & Digital Signatures

Team Project - Draft 1

- What kind of information system did your project team select to make?
- What is its purpose?
- What data types does it contain?
- What is its security categorization

Unit #	Team Project Schedule	Due
8	1st Rough Draft System Security Plan (SSP) review	3/15
10	2 nd Draft SSP review	3/29
11	3 rd Draft SSP review	4/5
12	Presentation of Final Deliverables	4/19
13	Presentation of Final Deliverables	4/26

Team Project

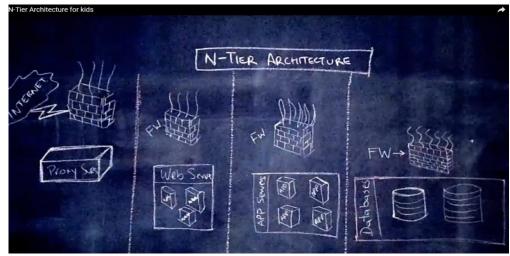

You can use https://app.diagrams.net/, other graphic drawing program, or PowerPoint

- Consider a web-based n-Tier system for your Team Project
- Identify who the users are

 In the weeks ahead, please get started drawing a 1st draft N-Tier Architecture for the web-based system, you will be adding security elements

Unit #	Team Project Schedule	Due
8	1 st Rough Draft System Security Plan (SSP) review	3/15
10	2 nd Draft SSP review	3/29
11	3 rd Draft SSP review	4/5
12	Presentation of Final Deliverables	4/19
13	Presentation of Final Deliverables	4/26

Case 1 Exercise: Draw a logical network diagram for the Titan System - adding in graphical elements that illustrate the system boundary, interconnections and data flow

You can use: https://app.diagrams.net/, another graphic drawing program, or PowerPoint

Use your drawing to help you answer the following questions:

- 1. What was the specific attack vector(s) used by attacker?
- 2. What failings existed in the following areas?
 - IT Governance
 - End users
 - Information technology services
 - Information security
 - Incident response

Draw a logical network diagram adding in graphical elements that illustrate the system boundary, interconnections and data flow

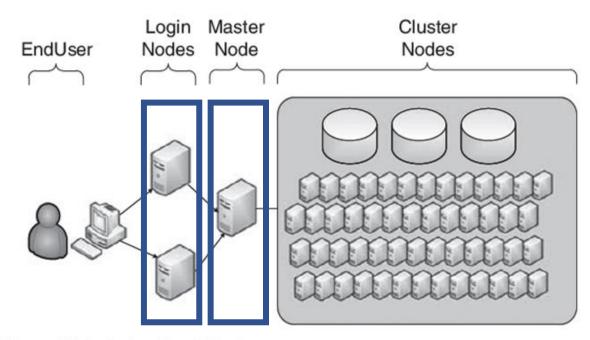

Figure 1 A typical grid architecture.

A High Performance Computing Cluster Under Attack: The Titan Incident

What was the specific attack vector(s) used by attacker:

- 1.
- 2.
- 3.
- 4.
- 5.
- 6.

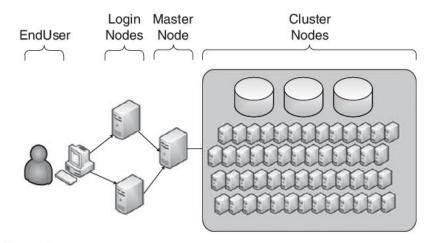

Figure 1 A typical grid architecture.

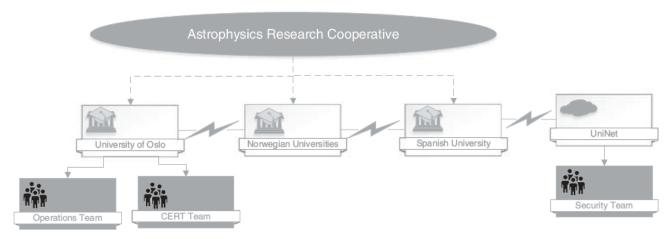

Figure 2 Geographic dispersion of Nordic DataGrid facility Tier-1 clusters.

A High Performance Computing Cluster Under Attack: The Titan Incident

Specific attack vector used by attacker:

- 1. Attacker obtained valid usernames and password combinations from a system in Spain that had a research agreement with University of Oslo (UiO)
- 2. Attacker accessed the Titan cluster as a research user using the valid credentials that were "harvested" from the previously compromised system in Spain
- 3. The attacker used a local Linux system exploit (CVE-2010-3847 GNU C library dynamic linker '\$ORIGIN' Expansion) to gain root administrative privileges on the Titan system (https://cwe.mitre.org/data/definitions/59)
- 4. Once administrative privileges were obtained, the attacker modified the SSH system files to collect the usernames and passwords of other end-users as they accessed the grid
- 5. The attacker created at least one "backdoor", or method of accessing the system without relying on the compromised accounts
- 6. The newly stolen credentials were used to gain unauthorized access to other systems, and they may also have been sold on the black market

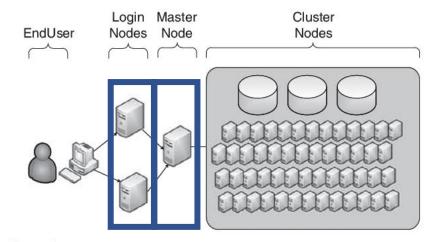

Figure 1 A typical grid architecture.

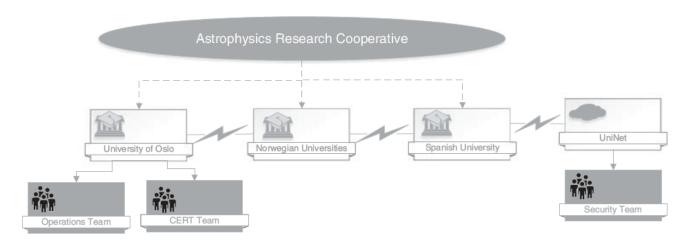

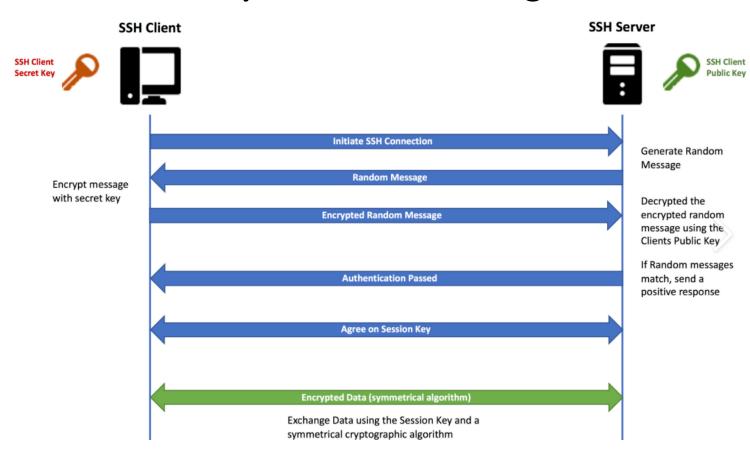

Figure 2 Geographic dispersion of Nordic DataGrid facility Tier-1 clusters.

...the attacker modified SSH system files to collect the usernames and passwords of other end-users as they accessed the grid

Secure Shell (SSH) is a cryptographic network protocol for operating network services securely over an unsecured network

Common applications include remote command-line login and remote command execution, but any network service can be secured with SSH.

The most visible application of the protocol is for access to shell accounts on Unix-like operating systems, but is in limited use on Windows as well

	Preventive Controls	Detective Controls	Corrective/Responsive Controls

IT Governance	 Analyze stakeholder needs and risks associated with not meeting those needs Educate staff and end users in security policies M	 IT security audit of high-risk security processes Security risk awareness 	 Stakeholder communication plan Response plan

Agenda

- ✓ Team Project It is not too early to get started...
- ✓ Case Study 1
- Cryptography terminology
- Symmetric Key Cryptography
 - Symmetric stream cryptography
 - Symmetric block cryptography
- Key sharing problem
- Public Key Cryptography
 - Diffie-Hellman algorithm: symmetric key generation through asynchronous cryptography
 - RSA algorithm
- Hybrid-Cryptography
 - Perfect Forward Secrecy
- Where do cryptographic controls go in the FedRAMP System Security Plan
- Brief review: Hashing & Digital Signatures

Remember: Services of cryptosystems

- Confidentiality Renders information unintelligible except by authorized entities
- **Authentication** Verifies the identity of the user or system that created, requested or provided the information
- Nonrepudiation Ensure the sender cannot deny sending the information
- **Integrity** Data has not been altered in an unauthorized manner since it was created, transmitted, or stored

Cipher = encryption algorithm

2 main attributes combined in a cypher

- 1. Confusion: usually carried out through substitution
- 2. Diffusion: Usually carried out through transposition

Example: Substitution cipher or algorithm

A mono-alphabetic substitution cipher

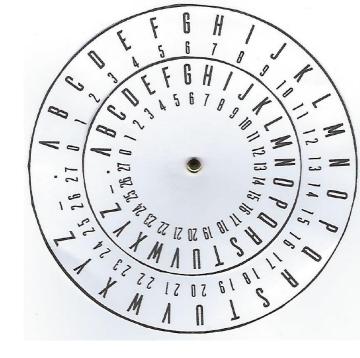

ABCDEFGHIJKLMNOPQRSTUVWXYZ ZYXWVUTSRQPONMLKJIHGFEDCBA

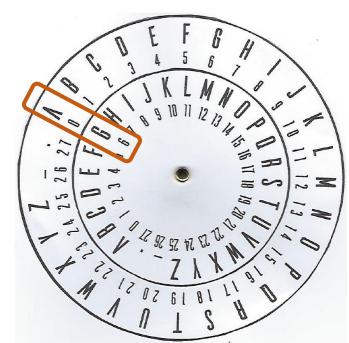

"SECURITY" <=> "HVXFIRGB"

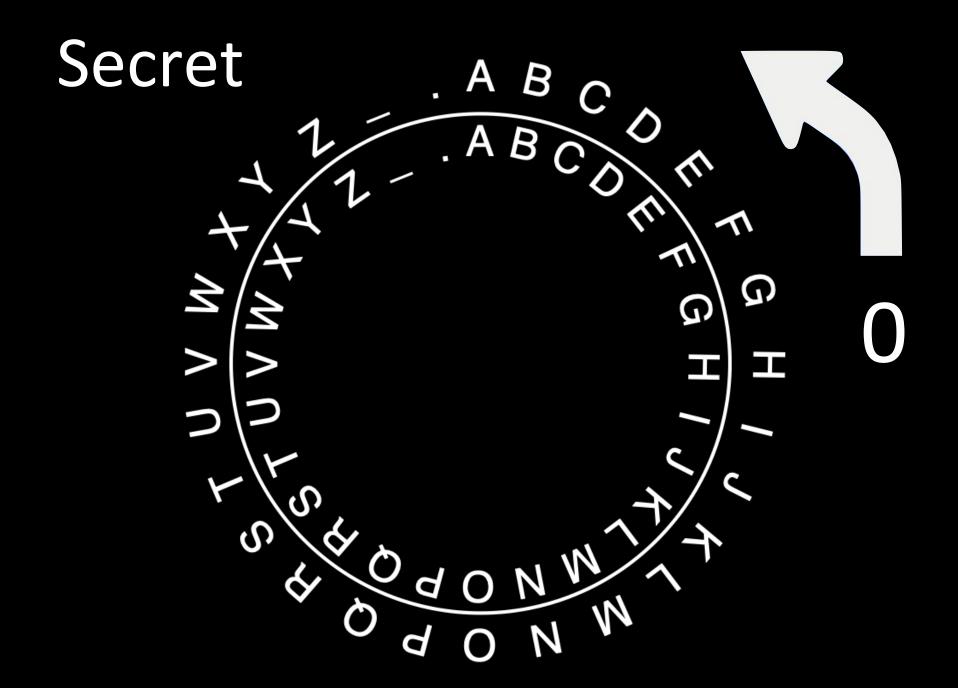

Cipher Disk based substitution

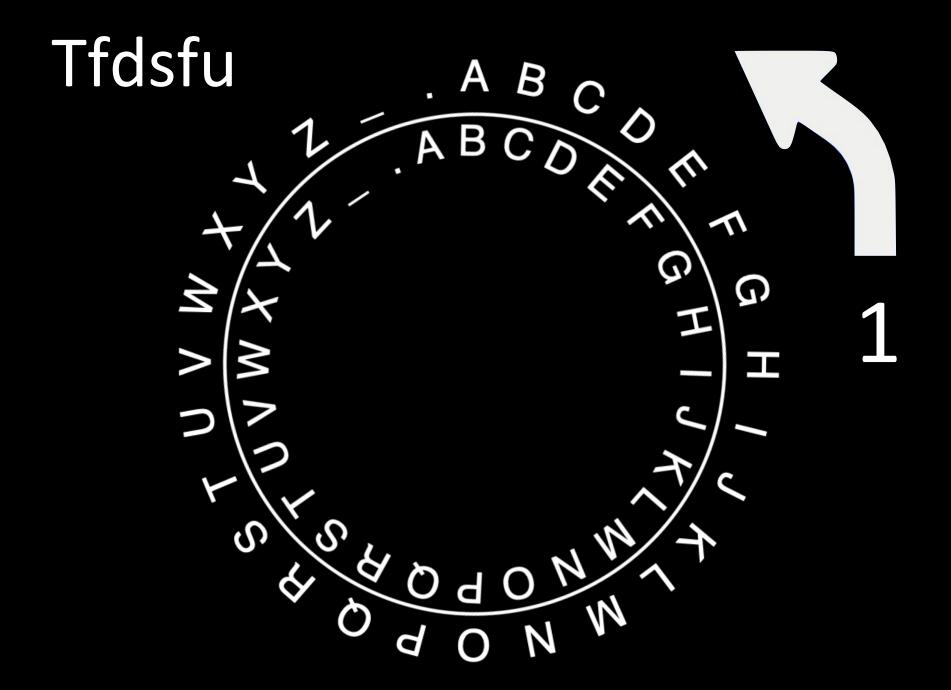

Outer wheel is for the *plaintext* alphabet Inner wheel is for *ciphertext*

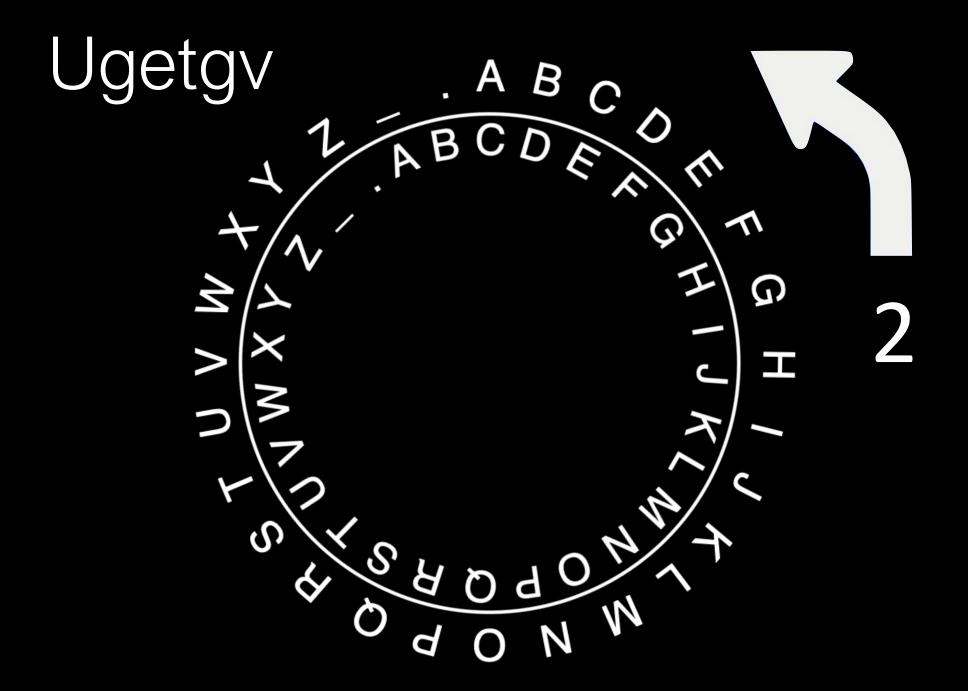

When the outer wheel and inner wheel and are both aligned at the letter "A" (i.e. position zero), there is no encryption mapping the letters on the outer wheel to letters on the inner wheel

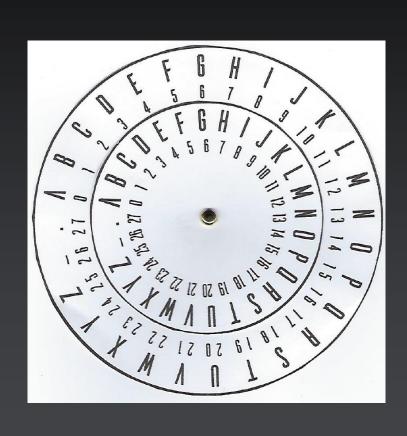

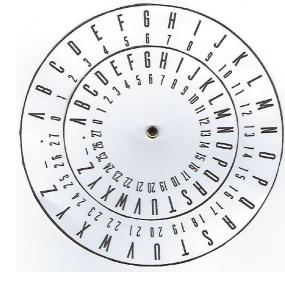

Keyspace is the number of possible keys

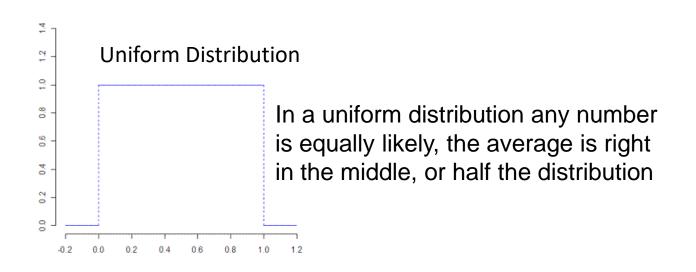

Question: Assuming each key is equally likely (randomly distributed) how many random guesses would be needed, on average, to find the key to decrypt the plaintext?

- \triangleright Answer: ~14, (28 -1) = 27 and 27/2 = 13.5 which is approximately 14
 - ➤ Because the average of a uniform distribution is half
 - ➤ Recall 26 letters in the alphabet + "." and "-" = 28, but we cannot use "0" as the key which gives us the original plaintext back the size of the alphabet

- This is important in cryptography because the average number of attempts needed to successfully guess the key through brute forcing is half of the key space
- This is true of the simple cipher wheel as well as modern encryption schemes with very large key spaces

What technique could you use to do it faster than 27 or 14 attempts?

If it was not just a lucky guess, then you were likely using "cryptanalysis", the science of breaking codes

What strategies could you use?

Linguistic cryptanalysis examples...

- Recognizing the beginning of the word
- Looking for letter pairs
- Looking at vowels

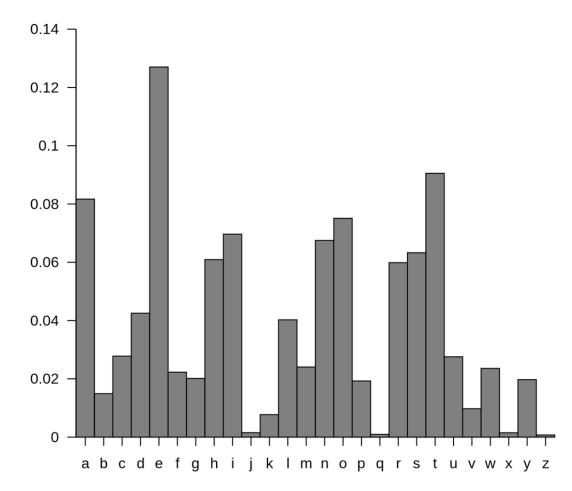

This form of cryptanalysis uses knowledge of the English language

Linguistic cryptanalysis examples...

One form of linguistic cryptanalysis is *frequency analysis of letters used in English* Frequency analysis recognizes that different letters have different probabilities of frequencies of use in words:

Given a sentences written in the English language

- E, T, A and O are the most common
- Z, Q and X are rare
- TH, ER, ON, and AN are the most common pairs of letters (termed bigrams or digraphs)
- SS, EE, TT, and FF are the most common repeats

Polyalphabetic Cipher

Ciphers can be made stronger, and frequency analysis made more difficult when more than one cipher alphabet is used

- For example, encrypt the plaintext message "SEND MONEY"
 - Using the word "SECURITY" as the key, but repeat its use in the key to make it have as many letters as the plaintext:

Plaintext: SEND MONEY (10 characters including the space "_")

Key: SECURITYSE (10 characters)

Polyalphabetic Cipher

Plaintext: SEND MONEY (10 characters including the space "_")

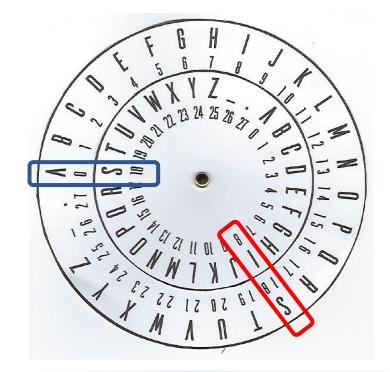

Key: SECURITYSE (10 characters)

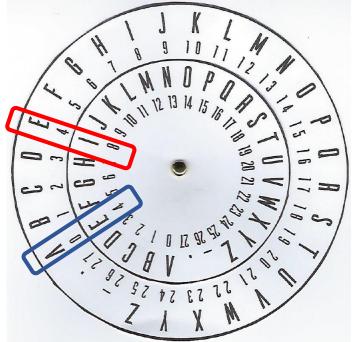

1. Encrypt by rotating the inner wheel so that "S" in the word "SECURITYSE" aligns with "A" on the outer wheel

Now "S" in the word "SEND" on the outer wheel maps to the letter "I" on the inner wheel, so "I" is the ciphertext

2. Next, rotate the inner wheel so that "E" in the word "SECURITYSE" aligns with "A" on the outer wheel.

Now "E" in the word "SEND" on the outer wheel maps to "I" on the inner wheel, so "I" is the ciphertext again, even though the plaintext is different than before

Polyalphabetic Cipher

Plaintext: SEND MONEY (10 characters including the space "_")

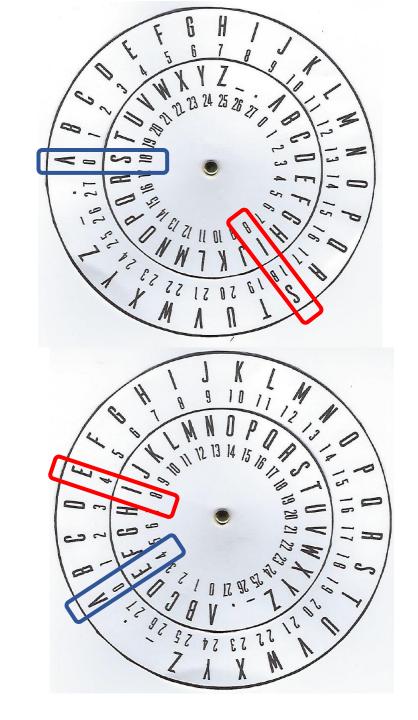

Key: SECURITYSE (10 characters)

What is the rest of the ciphertext for "SEND MONEY" using the polyalphabetic key "SECURITYSE"?

IIPXPUFJWA

Polyalphabetic ciphers make frequency analysis more difficult

Polyalphabetic substitution is another building block of cryptography

Random Polyalphabetic Cipher

Let's say our <u>plaintext</u> is:

We intend to begin on the first of February unrestricted submarine warfare.

And the polyalphabetic key is a string of random characters as long as the message: ackwulsjwkblogbzcukn.kqubpnnefjvcebuymaclzvzmzwfbxpmmzqwmm.tejzfutjcqrsf_hq

Question E: How can an attacker attempt to crack this message? Is an attack possible?

Cipher = encryption algorithm

- 2 main attributes combined in a cypher
 - 1. Confusion: usually carried out through substitution
 - 2. Diffusion: Usually carried out through transposition

Translating what we type, into ASCII, and then into binary... which is what is sent as data packets across the network to other computers...

Binary - Decimal

ASCII - Decimal

Logical XOR function — "Exclusive OR"

Creating "confusion" (i.e. substitution) through a binary mathematical function called "exclusive OR", abbreviated as XOR, symbolized as

Message stream: 1001010111

Keystream: 0011101010

Ciphertext stream: 1010111101

Agenda

- ✓ Team Project It is not too early to get started...
- ✓ Case Study 1
- √ Cryptography terminology
- Symmetric Key Cryptography
 - Symmetric stream cryptography
 - Symmetric block cryptography
- Key sharing problem
- Public Key Cryptography
 - Diffie-Hellman algorithm: symmetric key generation through asynchronous cryptography
 - RSA algorithm
- Hybrid-Cryptography
 - Perfect Forward Secrecy
- Where do cryptographic controls go in the FedRAMP System Security Plan
- Brief review: Hashing & Digital Signatures

Symmetric cryptography

Strengths:

- Much faster (less computationally intensive) than asymmetric systems.
- Hard to break if using a large key size.

Symmetric cryptography is 1,000 times faster than Asymmetric cryptography

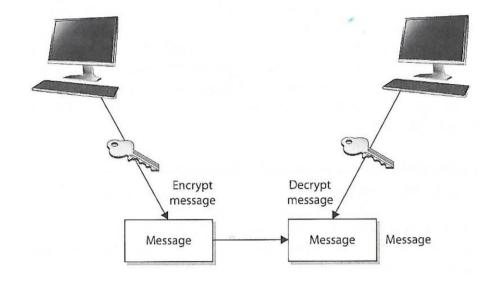

Weaknesses:

- Requires a secure mechanism to deliver keys properly.
- Each pair of users needs a unique key, so as the number of individuals increases, so does the number of keys, possibly making key management overwhelming.
- Provides confidentiality but not authenticity or nonrepudiation.

Two types: Stream and Block Ciphers

- **Stream Ciphers** treat the message a stream of bits and performs mathematical functions on each bit individually
- **Block Ciphers** divide a message into blocks of bits and transforms the blocks one at a time

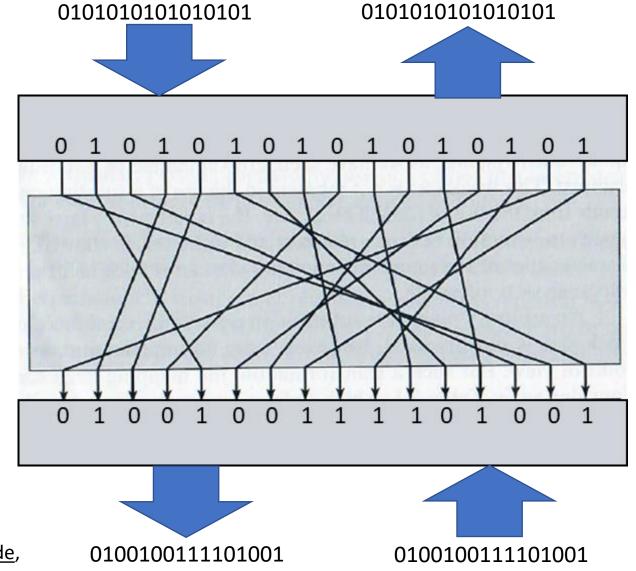

Symmetric encryption uses the same keys.

2 main attributes combined in a cypher

 Confusion: usually carried out through substitution

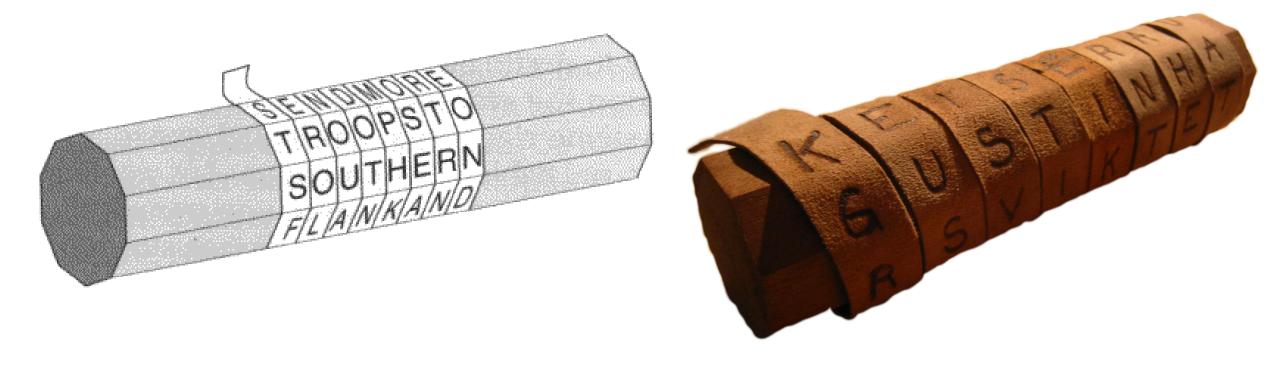

2. Diffusion: Usually carried out through <u>transposition</u>

Harris, S. and Maymi, F. (2016) <u>All-In-One CISSP Exam Guide</u>, McGraw Hill Education

Transposition

• Ancient example: <u>scytale</u>

Block Cyphers ("Cipher")

- In contrast, block ciphers encrypt a block of bits at a time
- Message is divided into blocks of bits
- Blocks are put through encryption functions 1 block at a time

Suppose you are encrypting a 640-bit long message to send using a block cypher that uses 64 bits

- Your message would be chopped up into 10 blocks each 64 bits long
- Each block, in turn, would be run through a series of encryption functions (substitution and transposition)
- Ending up with 10 blocks of ciphertext

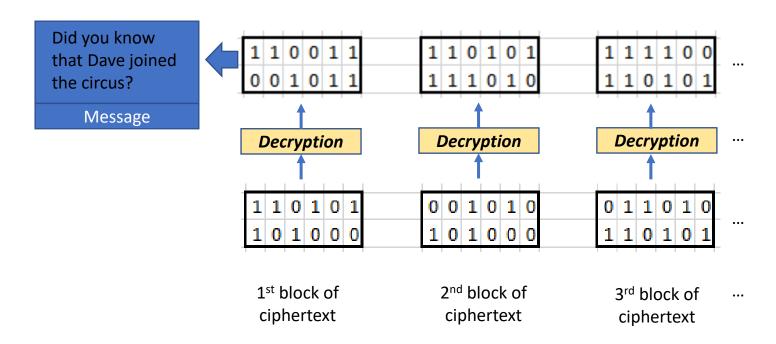

Block Ciphers

- Message is divided into blocks of bits
- Blocks are put through mathematical functions 1 block at a time

You send the message. Receiver uses the same block cipher and key (symmetric) to decipher the message

- The 10 ciphertext blocks go back through the algorithm in the reverse sequence
- Resulting in original plaintext message

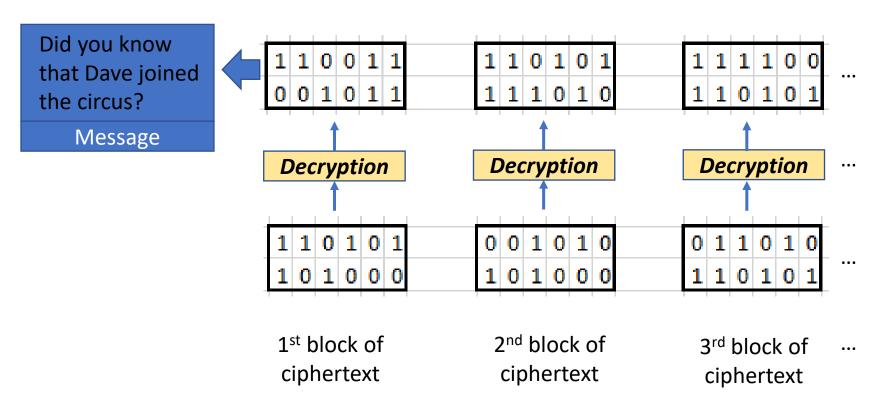

Block Ciphers

- Message is divided into blocks of bits
- Blocks are put through mathematical functions 1 block at a time

You send the message to your mother. She uses the same block cipher and key (symmetric) to decipher the message

- The 54 ciphertext blocks go back through the algorithm in the reverse sequence
- Resulting in your original plaintext message your message

MIS 5214 45

Modern Block Ciphers

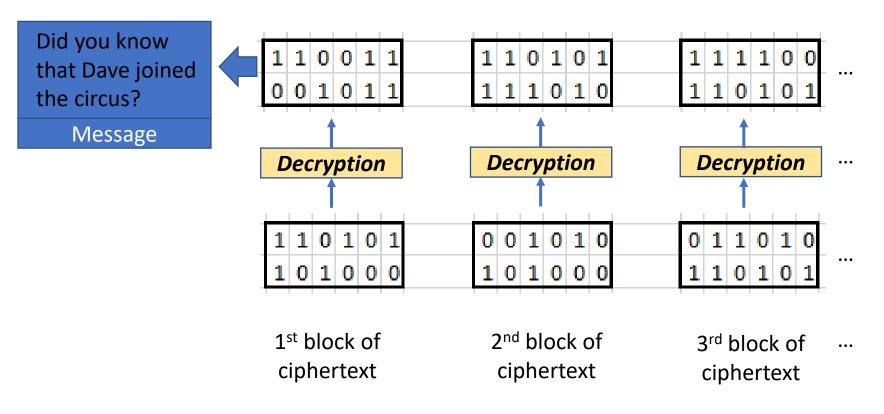

- Use block sizes of 128-bits or greater
 - Examples of Block Ciphers that can be used are:
 - AES (NIST's 2001 Advanced Encryption Standard originally known as Rijndael)
 - 128 bit block size, but 3 different key lengths: 128, 192, and 256 bits
 - Blowfish
 - Twofish
 - Serpent
- Do not use these examples of block ciphers which have a 56 bit key length, which is too small to provide secure encryption:
 - DES (Data Encryption Standard)
 - 3DES

Block Ciphers

- Message is divided into blocks of bits
- Blocks are put through mathematical functions 1 block at a time

You send the message to your mother. She uses the same block cipher and key (symmetric) to decipher the message

- The 54 ciphertext blocks go back through the algorithm in the reverse sequence
- Resulting in your original plaintext message your message

Modern Block Ciphers

- Use block sizes of 128-bits or greater
 - Examples of Block Ciphers that can be used are:
 - AES (NIST's 2001 Advanced Encryption Standard originally known as Rijndael)
 - 128 bit block size, but 3 different key lengths: 128, 192, and 256 bits
 - Blowfish
 - Twofish
 - Serpent
- Do not use these examples of block ciphers which have a 56 bit key length, which is too small to provide secure encryption:
 - DES (Data Encryption Standard)
 - 3DES

Block Ciphers versus Stream Ciphers

In this example, each Substitution Box (S-box) contains a lookup table used by the algorithm as instructions on how the bits are substituted

Plaintext	Ciphertext
0000	1110

...followed by transposition...

Block cipher's "mode of operation"

5 modes of operation are used to tailor them for use in different applications:

- 1. ECB Electronic Code Book mode
- 2. CBC Cipher Block Chaining mode
- 3. CFB Cipher FeedBack mode
- 4. OFB Output FeedBack mode
- 5. CTR CounTeR mode

ECB – Electronic Code Book mode

 A data block of a certain size (e.g. 64 bits or 128 bits or...) is entered into the algorithm with the key, and a block of cipher text is produced

$$C_i = Encrypt(Key, P_i)$$

for $i = 1, ..., k$

Where:

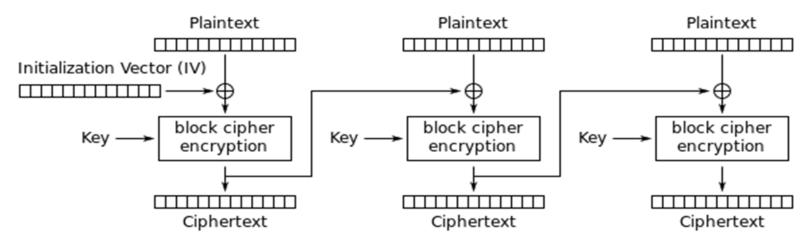

- Ci is block i of ciphertext
- P, is a block of plaintext

- Encrypts every block the same way every time for a given key
- Why is this a problem?
 - This is a problem because **frequency analysis** of the encrypted text can reveal a lot of information
 - Not enough randomness

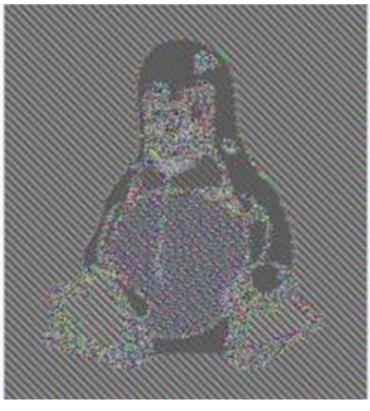

CBC – Cipher Block Chaining mode

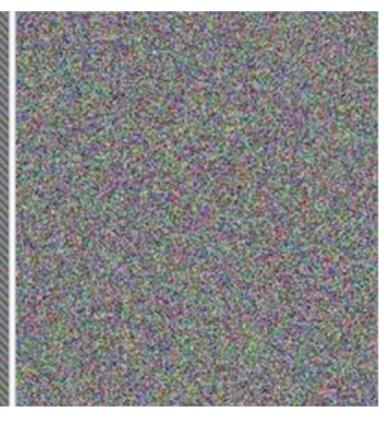

- Is much more secure
- Does not reveal a pattern of encryption for frequency analysis
- Each block of text, the key, and the value based on the previous block are processed in the algorithm and applied to the next block of text

- XORs a plaintext with the last encrypted block before encrypting it. This ensures that the same plaintext
 is encrypted differently every time.
- Requires an initialization vector (or IV) to get started, since the first block doesn't have a previous encrypted block to XOR against.

Original Image

Block cipher with ECB (Electronic Code Book) encryption

Not good!

Block cipher with CBC (Cipher Block Chaining) or any of the other modes of encryption

These are good!

Cryptanalysis Attacks

- Brute force
 - Trying all key values in the keyspace
- Frequency Analysis
 - Guess values based on frequency of occurrence
- Dictionary Attack
 - Find plaintext based on common words
- Known Plaintext
 - Format or content of plaintext available
- Chosen Plaintext
 - Attack can encrypt chosen plaintext
- Chosen Ciphertext
 - Decrypt known ciphertext to discover key

- Random Number Generator (RNG) Attack
 - Predict initialization vector used by an algorithm
- Social Engineering
 - Humans are the weakest link

Modern Block Ciphers

Use block sizes of 128-bits or greater

- Examples of Block Ciphers that can be used are:
 - AES
 - Blowfish
 - Twofish
 - Serpent

Do not use these examples of block ciphers which use 64-bit blocks, which are too small to be secure include:

- DES
- 3DES

Practical Cryptanalysis

DES Cracker:

- A DES key search machine
- Contains 1,536 chips
- Cost: \$250,000
- · Searches 88 billion keys per second
- In 1998, Electronic Freedom Foundation (EFF) won \$10,000 in RSA Laboratory's "DES Challenge II-2" by successfully finding a DES key through brute force in 56 hours
- AWT-4500 DEEP CRACK ORBIT 61335A 9816 T03093.1A

- DES uses a 56-bit key, meaning that there are 256 possible keys under which a message can be encrypted.
 - This is: 72,057,594,037,927,936, or approximately 72 quadrillion possible keys
- One of the major criticisms of DES, when proposed in 1975, was that the key size was too short
 - Martin Hellman and Whitfield Diffie of Stanford
 University estimated that a machine fast enough to test
 that many keys in a day would have cost about \$20
 million in 1976,
 - An affordable sum to national intelligence agencies
- Subsequent advances in the price/performance of chips kept reducing that cost until, twenty years later, it became affordable for even a small nonprofit organization such as the EFF to mount a realistic attack

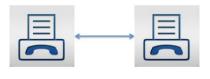

DES Cracker:

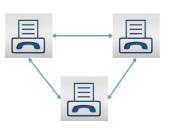

- A DES key search machine
- Contains 1,536 chips
- Cost: \$250,000
- Searches 88 billion keys per second
- Won RSA Laboratory's "**DES Challenge II-2**" by successfully finding a DES key in 56 hours

Key sharing problem

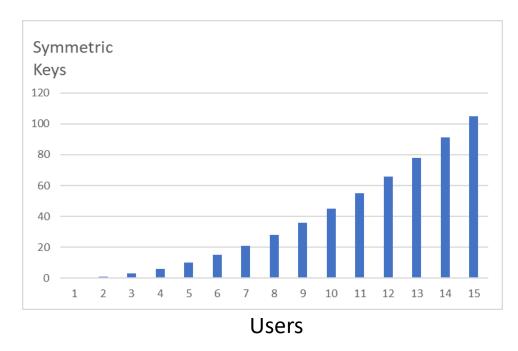

Sharing cryptographic keys has been a problem throughout history

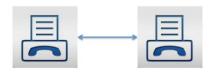

• The number of pairs of keys ("secure network connections") grows at a near exponential rate (i.e. geometric rate) as the number of users

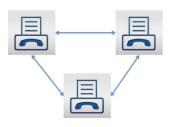

increases

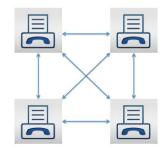

Users	Symmetric
	Keys
1	0
2	1
3	3
4	6
5	10
6	15
7	21
8	28
9	36
10	45
11	55
12	66
13	78
14	91
15	105

Key sharing problem 🚨 🦳 🖶

- The number of pairs of keys needed for "n" users is determined by an equation known as Metcalf's Law
- Number of key pairs needed for n users = (n*(n-1))/2
 - The reason for the n-1 is that you do not need to communicate with yourself
- For MIS 4596 with 22 students how many keys would we need:

$$(22 *21)/2 = 231 \text{ keys}$$

MIS 4596 60

MIS 4596

Diffie-Hellman Algorithm: Secret symmetric key derivation through public key sharing

Assumptions:

A prime number is a positive whole number whose only factors (i.e. integer divisors) are 1 and the number itself (e.g. 2, 3, 5, 7, 11, 13, 17, 19, 23, ...). Bob & Alice want to compute a shared secret key to protect confidentiality of their conversation. Eve eavesdrops...

Algorithm:

- 1. Bob & Alice publicly agree on " \mathbf{p} " called *prime modulus* (e.g. $\mathbf{p} = 23$) & " \mathbf{g} " called *generator* (e.g. $\mathbf{g} = 5$), Eve overhears
 - . Bob & Alice each choose their own secret key:
 - Bob's secret key is referred to as "x_bob" which is a number between 1 and p-1 (e.g. x_bob = 12)
 - Alice's secret key is referred to as "x_alice" which also is a number between 1 and p-1 (e.g. x_alice = 7)
- 3. Bob & Alice each computes their own public key, which they share with each other and Eve intercepts...
 - Bob computes: $y_bob = g^{x_bob} \mod p$ which is: $y_bob = 5^{12} \mod 23 = 18$ which he shares with Alice (and Eve)
 - Alice computes: $y_alice = g_a^{x_alice} \mod p$ which is: $y_alice = 5^7 \mod 23 = 17$ which she shares with Bob (and Eve)
- 4. Bob & Alice each compute their shared secret symmetric key
 - Bob computes: y_alicex_bob mod p which is: 17¹² mod 23 = 6
 - Alice computes: y_bob^{x_alice} mod p which is: 18⁷ mod 23 = 6
- 5. Bob & Alice now have a **shared secret ("symmetric") key = 6**
- 6. Eve has Bob & Alice's public keys: y_bob=18 & y_alice=17, prime modulus: p=23 and generator: g=5, but not their secret keys x_bob = 12 & x_alice = 7
 - Eve cannot calculate Bob& Alice's shared symmetric secret key from their public keys, p and g alone even though she knows they are using the Diffie-Hellman algorithm!

In practice, p must be much larger prime number... this is a 4096-bit p

Diffie-Hellman

- Uses asymmetric public and private keys to exchange a symmetric key
- Does not use asymmetric keys for confidentiality (i.e. to encrypt or decrypt any messages)
- Users/systems need to negotiate a new key for every new person
- No authentication, no non-repudiation

Diffie-Hellman was vulnerable to man-in-the-middle attack, because no authentication occurs before public keys are exchanged

- 1. Tanya sends her public key to Erika, but Lance grabs the key during transmission so it never makes it to Erika
- 2. Lance spoofs Tanya's identity and sends over his public key to Erika. Erika now thinks she has Tanya's public key
- 3. Erika sends her public key to Tanya, but Lance grabs the key during transmission so it never makes it to Tanya
- 4. Lance spoofs Erika's identity and sends over his public key to Tanya. Tanya now thinks she has Erika's public key
- 5. Tanya combines her private key and Lance's public key and creates a symmetric key S1
- 6. Lance combines his private key and Tanya's public key and creates symmetric key S1
- 7. Erika combines her private key and Lance's public key and creates symmetric key S2
- 8. Lance combines his private key and Erika's public key and creates symmetric key S2
- 9. Now Tanya and Lance share a symmetric key (S1) and Eriak and Lance share a different symmetric key (S2). Tanya and Erika think they are sharing a key between themselves and od not realize Lance is involved
- 10. Tanya writes a message to Erika, and uses her symmetric key (S1) to encrypt the message, and sends it
- 11. Lance grabs the message and decrypts it with symmetric key S1, reads or modifies the message and re-encrypts it with symmetric key S2, and then sends it to Erika
- 12. Erika take symmetric key S2 and uses it to decrypt and read the message....

Symmetric versus asymmetric algorithms

Symmetric cryptography

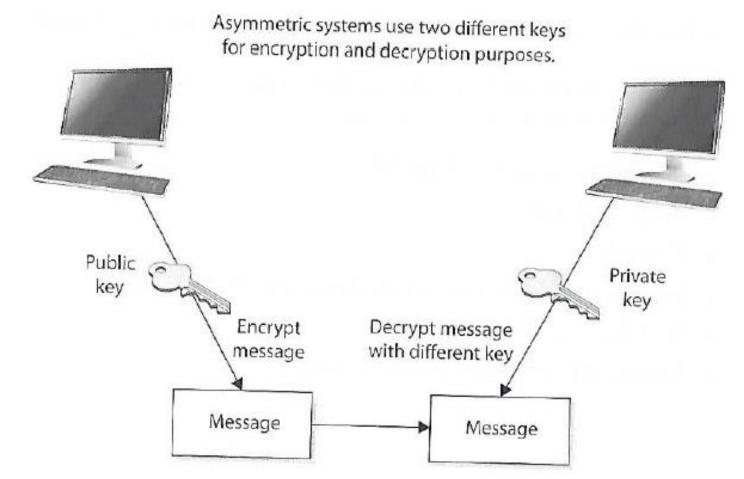

- Use a copied pair of symmetric (identical) secret keys
- The sender and the receive use the same key for encryption and decryption functions
- Confidentiality, but no integrity, authentication nor non-repudiation

Asymmetric cryptography

- Also know as "public key cryptography"
- Use different ("asymmetric") keys for encryption and decryption
- One is called the "private key" and the other is the "public key"
- Confidentiality, but also want authenticity and non-repudiation

Asymmetric cryptography

- Public and Private keys are mathematically related
 - Public keys are generated from private key
 - Private keys cannot be derived from the associated public key (if it falls into the wrong hands)
- Public key can be known by everyone
- Private key must be known and used only by the owner

Asymmetric cryptography is computationally intensive and much slower (1,000 times slower) than symmetric cryptography

Quick review

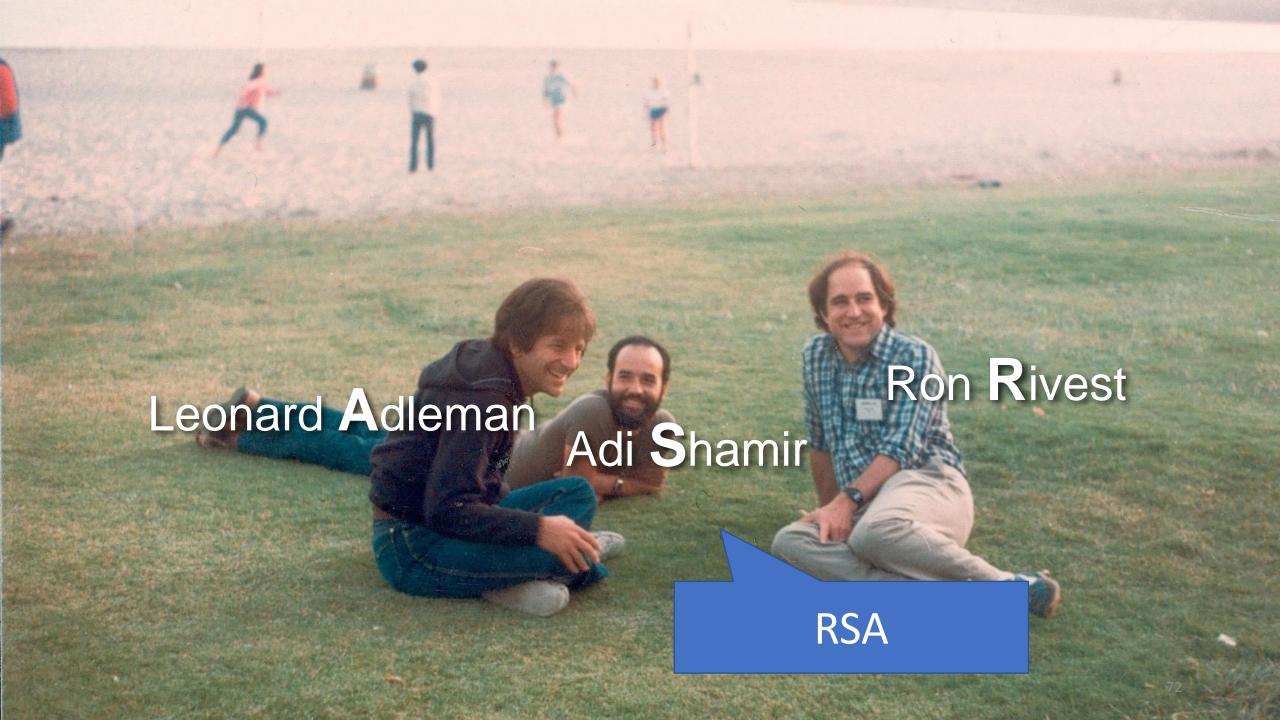

- 1. If a symmetric key is encrypted with a receiver's public key, what security service is provided?
 - **Confidentiality**: only the receiver's private key can be used to decrypt the symmetric key, and only the receiver should have access to this private key

Quick review

- 2. If data is encrypted with the sender's private key, what security services are provided?
 - **Authenticity** of the sender and nonrepudiation. If the receiver can decrypt the encrypted data with the sender's public key, then receiver knows the data was encrypted with the sender's private key

Quick review

- 3. Why do we encrypt the message with the symmetric key rather than the asymmetric key?
 - Because the asymmetric key algorithm is too slow

RSA Public Key Algorithm

- Most popular worldwide standard, that can be used for:
 - Asymmetric encryption/decryption
 - Key exchange (i.e. used to encrypt AES symmetric key)
 - Digital signatures
- In one direction, RSA provides:
 - Confidentiality through encryption
 - Authentication and non-repudiation through signature verification
- In the inverse direction, RSA provides:
 - Confidentiality through decryption
 - Authentication and non-repudiation through signature generation

RSA Public Key Algorithm

- Based on factoring large numbers into their prime numbers
 - A prime number is a positive whole number whose only factors (i.e. integer divisors) are 1 and the number itself
 - E.g. 2, 3, 5, 7, 11, 13, 17, 19, 23, ...
 - Prime number factoring is
 - Easy when you know the result and one of the factors
 - 6,700,283 = 1889 * 3547
 - Difficult when you do not know the factors, and the result is large
 - 6,700,283 = prime1 * prime2

Public Key algorithms

- Fundamental security elements in cryptosystems, applications and protocols
- Assure confidentiality, authenticity and non-repudiation of electronic communications and data storage
- Provide:
 - Key distribution and secrecy (e.g. Diffie—Hellman key exchange)
 - Digital signatures (e.g. Digital Signature Algorithm)
 - Both: key distribution and secrecy and digital signatures (e.g., RSA, ECC)

Elliptic-curve cryptography (ECC)

- Alternate approach to public-key cryptography based on algebraic structure of elliptic curves (based on Galois fields)
- Provides much the same security functionality as Diffie-Hellman and RSA:
 - Encryption/decryption (confidentiality)
 - Secure key distribution (authenticity, confidentiality)
 - Digital signatures (authenticity, non-repudiation)

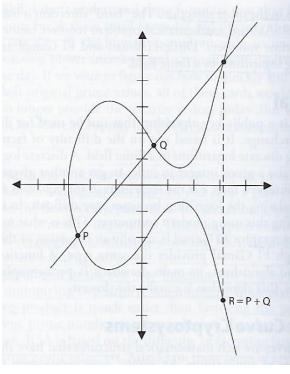

- ECC's is much more efficient than RSA and the other asymmetric algorithms
 - Requires less bits and smaller keys than RSA for achieving the same level of security in its calculations and other algorithms
 - ECC's efficiency makes it very good for wireless devices and cellular phones with limited processing capacity, storage, power supply and bandwidth

Elliptic-curve cryptography (ECC)

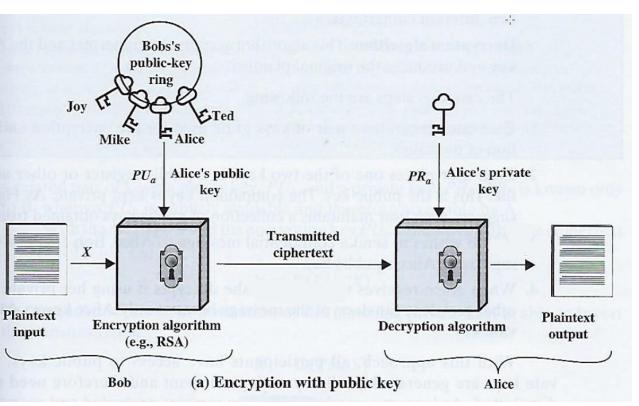

Elliptic-curve Diffie—Hellman (ECDH) is a variant of the Diffie—Hellman public key protocol using elliptic-curve cryptography

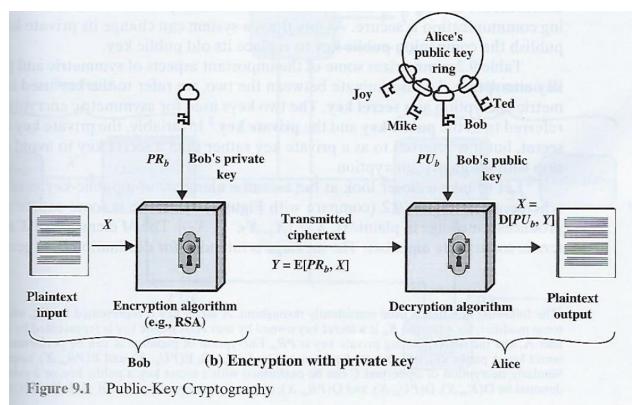

- A key agreement protocol that allows two parties, each having an elliptic-curve public-private key pair, to establish a shared secret over an insecure channel
- The shared secret may be directly used as a key, or to derive another key
- The key, or the derived key, can then be used to encrypt subsequent communications using a symmetric-key cipher

Example of an elliptic curve

Public Key Management

 - ✓ RSA algorithm
- Hybrid-Cryptography
 - Perfect Forward Secrecy
- Where do cryptographic controls go in the FedRAMP System Security Plan
- Brief review: Hashing & Digital Signatures

Hybrid Encryption (a.k.a. "digital envelope")

Symmetric and asymmetric and algorithms are often used together

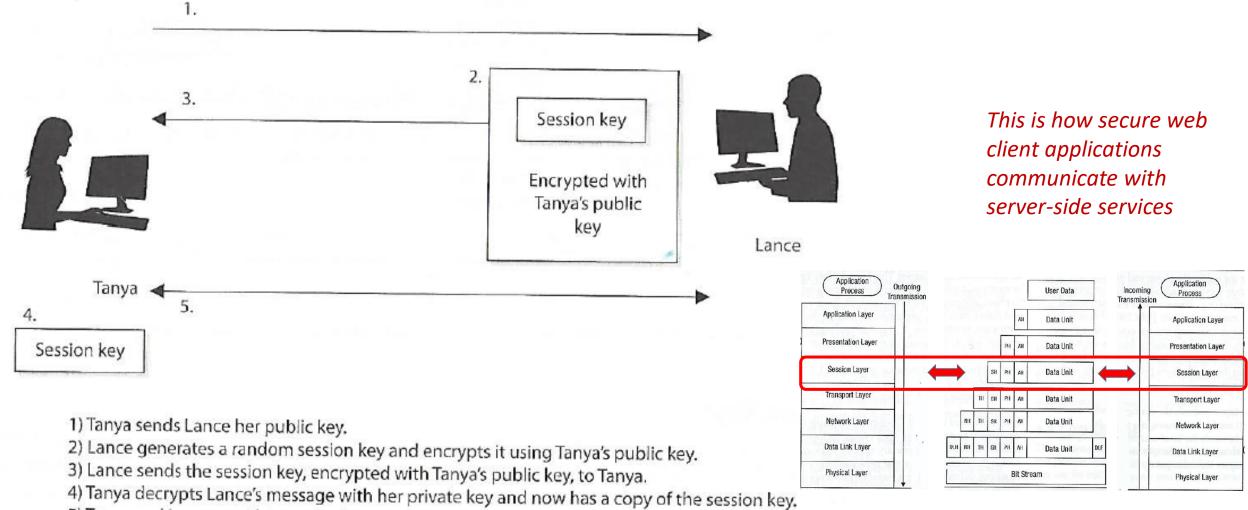

- Public key cryptography's asymmetric algorithm is used to create public and private keys for secure automated key distribution
- Symmetric algorithm is used to create secret keys for rapid encryption/decryption of bulk data

MIS 4596

Session keys

<u>Single-use</u> symmetric keys used to encrypt messages between two users in an individual communication session

MIS 4596

5) Tanya and Lance use this session key to encrypt and decrypt messages to each other.

Perfect Forward Secrecy (PFS) or Forward Secrecy (FS)

Designed to prevent the compromise of a long-term secret key from affecting the confidentiality of past conversations

- Protects encrypted data recorded in past sessions against future attacks and compromises of private or secret keys
- Diffie-Hellman and RSA are used together to protect encrypted communications and sessions recorded in the past from being retrieved and decrypted in the future if long-term secret or private keys are compromised in the future

https://www.wired.com/2016/11/what-is-perfect-forward-secrecy/

Example of a simple instant messaging protocol employing forward secrecy:

- 1. Alice and Bob each generate a pair of long-term, asymmetric public and private keys, verification establishes confidence that the claimed owner of a public key is the actual owner
- 2. Alice and Bob use a key exchange algorithm such as Diffie–Hellman, to securely agree on a short-term symmetric session key
 - They use the asymmetric keys from step 1 only to authenticate one another during this process
- 3. Alice sends Bob a message, encrypting it with a symmetric cipher using the session key negotiated in step 2
- 4. Bob decrypts Alice's message using the key negotiated in step 2
- 5. The symmetric session key exchange process repeats for each new message sent, starting from step 2 (switching Alice and Bob's roles as sender/receiver as appropriate)
 - Step 1 is never repeated
- Forward secrecy is achieved by generating new session keys for each message
 - It ensures that past communications cannot be decrypted if one of the keys generated in an iteration of step 2 is compromised, since such a key is only used to encrypt a single message
 - It also ensures that past communications cannot be decrypted if the long-term private keys from step 1 are compromised
- However, masquerading as Alice or Bob would be possible going forward if this occurred, possibly compromising all future messages

Perfect Forward Secrecy

- Forward secrecy is present in several major protocol implementations:
 - SSH
 - IPsec (RFC 2412) as an optional feature
 - Transport Layer Security (TLS)
 - Cipher suites based on Diffie—Hellman key exchange (DHE-RSA, DHE-DSA)
 - Elliptic curve Diffie—Hellman key exchange (ECDHE-RSA, ECDHE-ECDSA)
 - OpenSSL supports forward secrecy using elliptic curve Diffie—Hellman since V1.0
 - Off-the-Record Messaging, a cryptography protocol and library for many instant messaging clients

Perfect Forward Security in use...

The latest news and insights from Google on security and safety on the Internet

Protecting data for the long term with forward secrecy

November 22, 2011

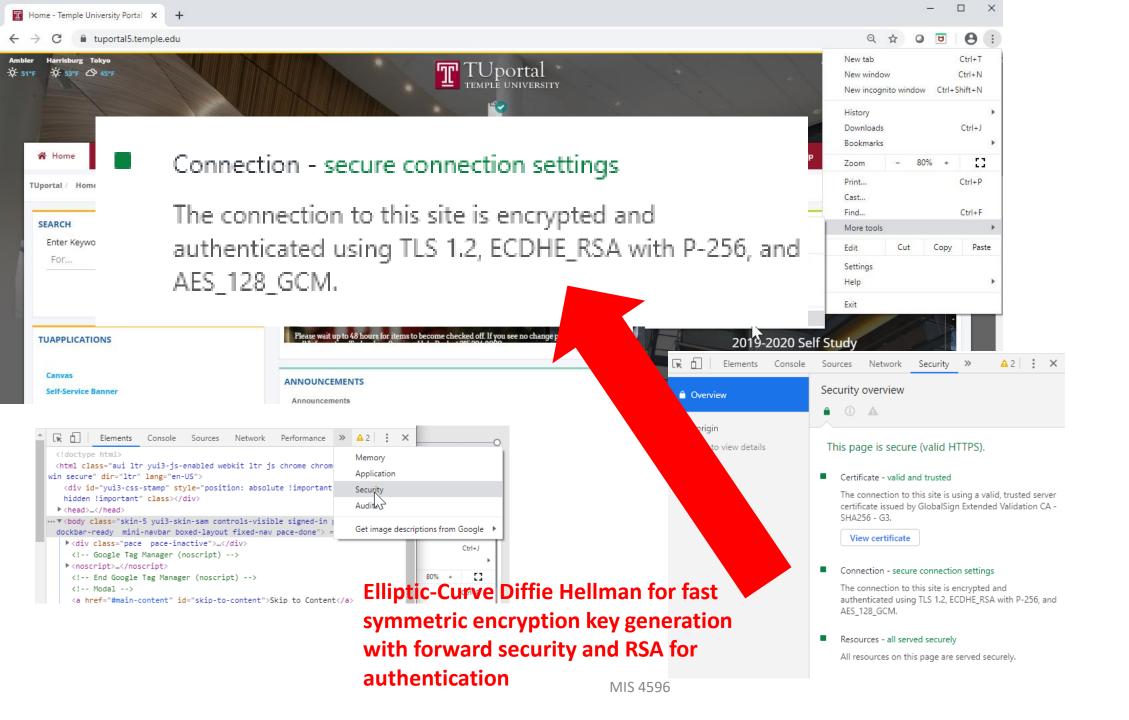

Posted by Adam Langley, Security Team

Last year we introduced HTTPS by default for Gmail and encrypted search. We're pleased to see that other major communications sites are following suit and deploying HTTPS in one form or another. We are now pushing forward by enabling forward secrecy by default.

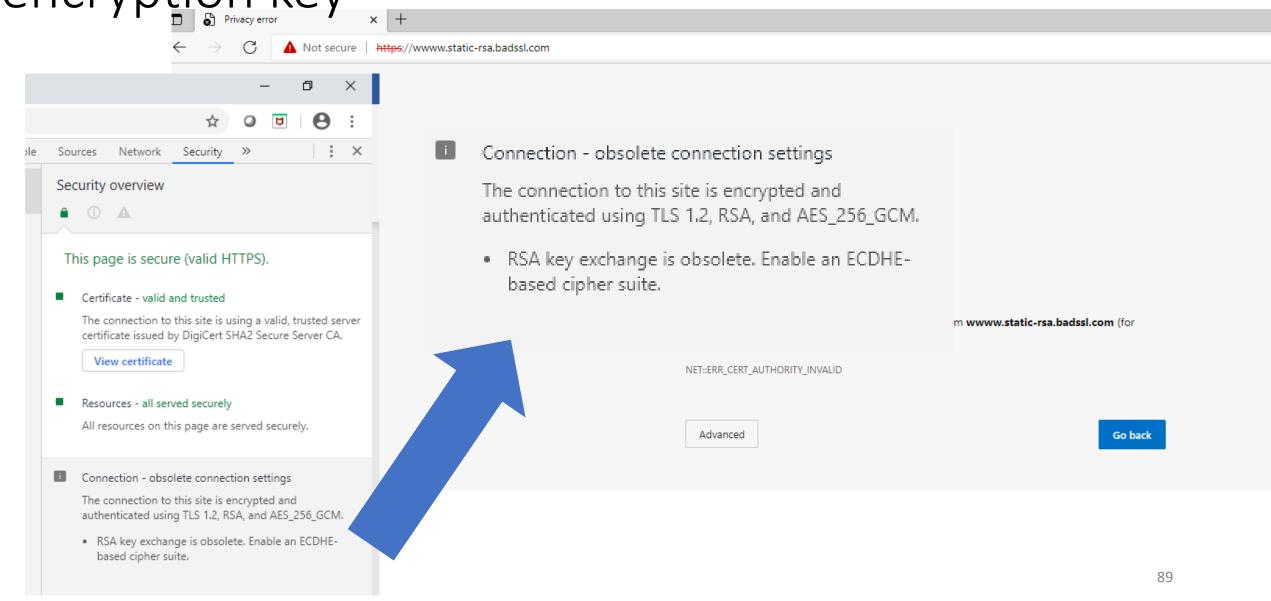

Most major sites supporting HTTPS operate in a non-forward secret fashion, which runs the risk of retrospective decryption. In other words, an encrypted, unreadable email could be recorded while being delivered to your computer today. In ten years time, when computers are much faster, an adversary could break the server private key and

The new wireless encryption standard WPA3 uses Perfect Forward Security for all wireless clients

Services of cryptosystems

- ✓ **Confidentiality** Renders information unintelligible except by authorized entities
- ✓ **Authentication** Verifies the identity of the user or system that created, requested or provided the information
- ✓ Nonrepudiation Ensure the sender cannot deny sending the information
- **Integrity** Data has not been altered in an unauthorized manner since it was created, transmitted, or stored

SC-12 CRYPTOGRAPHIC KEY ESTABLISHMENT AND MANAGEMENT

<u>Control</u>: The organization establishes and manages cryptographic keys for required cryptography employed within the information system in accordance with [Assignment: organization-defined requirements for key generation, distribution, storage, access, and destruction].

<u>Supplemental Guidance</u>: Cryptographic key management and establishment can be performed using manual procedures or automated mechanisms with supporting manual procedures. Organizations define key management requirements in accordance with applicable federal laws, Executive Orders, directives, regulations, policies, standards, and guidance, specifying appropriate options, levels, and parameters. Organizations manage trust stores to ensure that only approved trust anchors are in such trust stores. This includes certificates with visibility external to organizational information systems and certificates related to the internal operations of systems. Related controls: SC-13, SC-17.

Control Enhancements:

(1) CRYPTOGRAPHIC KEY ESTABLISHMENT AND MANAGEMENT | AVAILABILITY

The organization maintains availability of information in the event of the loss of cryptographic keys by users.

<u>Supplemental Guidance</u>: Escrowing of encryption keys is a common practice for ensuring availability in the event of loss of keys (e.g., due to forgotten passphrase).

(2) CRYPTOGRAPHIC KEY ESTABLISHMENT AND MANAGEMENT | SYMMETRIC KEYS

The organization produces, controls, and distributes symmetric cryptographic keys using [Selection: NIST FIPS-compliant; NSA-approved] key management technology and processes.

(3) CRYPTOGRAPHIC KEY ESTABLISHMENT AND MANAGEMENT | ASYMMETRIC KEYS

The organization produces, controls, and distributes asymmetric cryptographic keys using [Selection: NSA-approved key management technology and processes; approved PKI Class 3 certificates or prepositioned keying material; approved PKI Class 3 or Class 4 certificates and hardware security tokens that protect the user's private key].

(4) CRYPTOGRAPHIC KEY ESTABLISHMENT AND MANAGEMENT | PKI CERTIFICATES [Withdrawn: Incorporated into SC-12].

(5) CRYPTOGRAPHIC KEY ESTABLISHMENT AND MANAGEMENT | PKI CERTIFICATES / HARDWARE TOKENS [Withdrawn: Incorporated into SC-12].

SC-13 CRYPTOGRAPHIC PROTECTION

<u>Control</u>: The information system implements [Assignment: organization-defined cryptographic uses and type of cryptography required for each use] in accordance with applicable federal laws, Executive Orders, directives, policies, regulations, and standards.

Supplemental Guidance: Cryptography can be employed to support a variety of security solutions including, for example, the protection of classified and Controlled Unclassified Information, the provision of digital signatures, and the enforcement of information separation when authorized individuals have the necessary clearances for such information but lack the necessary formal access approvals. Cryptography can also be used to support random number generation and hash generation. Generally applicable cryptographic standards include FIPS-validated cryptography and NSA-approved cryptography. This control does not impose any requirements on organizations to use cryptography. However, if cryptography is required based on the selection of other security controls, organizations define each type of cryptographic use and the type of cryptography required (e.g., protection of classified information: NSA-approved cryptography; provision of digital signatures: FIPS-validated cryptography). Related controls: AC-2, AC-3, AC-7, AC-17, AC-18, AU-9, AU-10, CM-11, CP-9, IA-3, IA-7, MA-4, MP-2, MP-4, MP-5, SA-4, SC-8, SC-12, SC-28, SI-7.

Control Enhancements: None.

- CRYPTOGRAPHIC PROTECTION | FIPS-VALIDATED CRYPTOGRAPHY [Withdrawn: Incorporated into SC-13].
- (2) CRYPTOGRAPHIC PROTECTION | NSA-APPROVED CRYPTOGRAPHY [Withdrawn: Incorporated into SC-13].
- (3) CRYPTOGRAPHIC PROTECTION | INDIVIDUALS WITHOUT FORMAL ACCESS APPROVALS [Withdrawn: Incorporated into SC-13].
- (4) CRYPTOGRAPHIC PROTECTION | DIGITAL SIGNATURES [Withdrawn: Incorporated into SC-13].

SC-12 (1) CONTROL ENHANCEMENT (H)
The organization maintains availability of information in the event of the loss of cryptographic keys by users.

SC-12 (2) CONTROL ENHANCEMENT (M) (H) The organization produces, controls, and distributes symmetric cryptographic keys using [FedRAMP Selection: NIST FIPS-compliant] key management technology and processes.

SC-12 (3) CONTROL ENHANCEMENT (M) (H)
The organization produces, controls, and distributes
asymmetric cryptographic keys using [Selection: NSAapproved key management technology and processes;
approved PKI Class 3 certificates or prepositioned
keying material; approved PKI Class 3 or Class 4
certificates and hardware security tokens that protect
the user's private key].

SC-13 Use of Cryptography (L) (M) (H)
The information system implements [FedRAMP
Assignment: FIPS-validated or NSA-approved
cryptography] in accordance with applicable federal
laws, Executive Orders, directives, policies,
regulations, and standards.

- Brief review: Hashing & Digital Signatures

Quick Review: One-way Hash

- Assures message integrity
- A function that takes a variable-length string (i.e. message) and produces a fixedlength value called a hash value
- Does not use keys

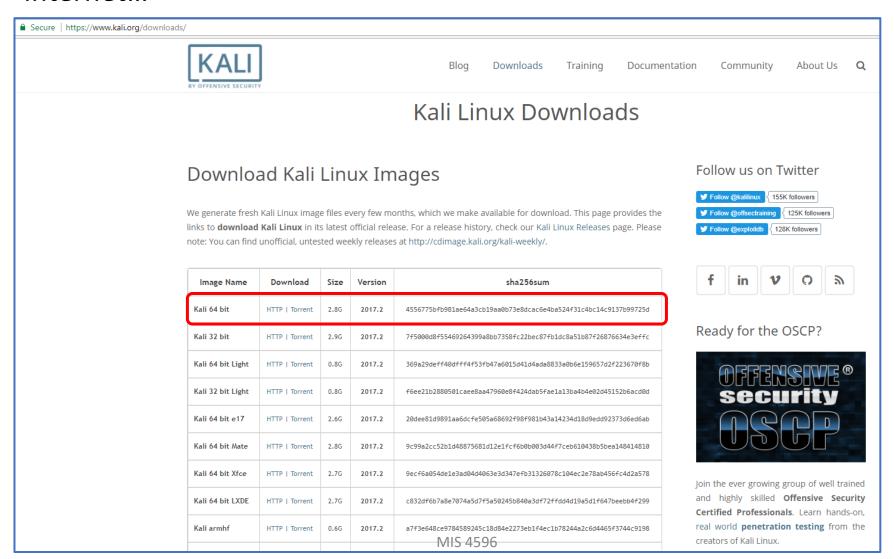

- Sender puts message through hashing function
- 2. Message digest generated
- Message digest appended to the message
- 4. Sender sends message to receiver
- Receiver puts message through hashing function
- 6. Receiver generates message digest value
- 7. Receiver compares the two message digests values. If they are the same, the message has not been altered

Note: Hashing results in fixed-sized output

- Names for the output of a hashing functions include "hash" and a message digest (md), because a hash "digests" an input of any size down to a fixed-sized output
 - No matter the size of the input, the out put is the same, for example the md5 hash function's output:
 - Letter 'a' in binary: 01000001 => md5 hash => 32-character string
 - Blu-ray disk digest => md5 hash => 32-character string
 - 6 TB hard drive digest => md5 hash => 32-character string

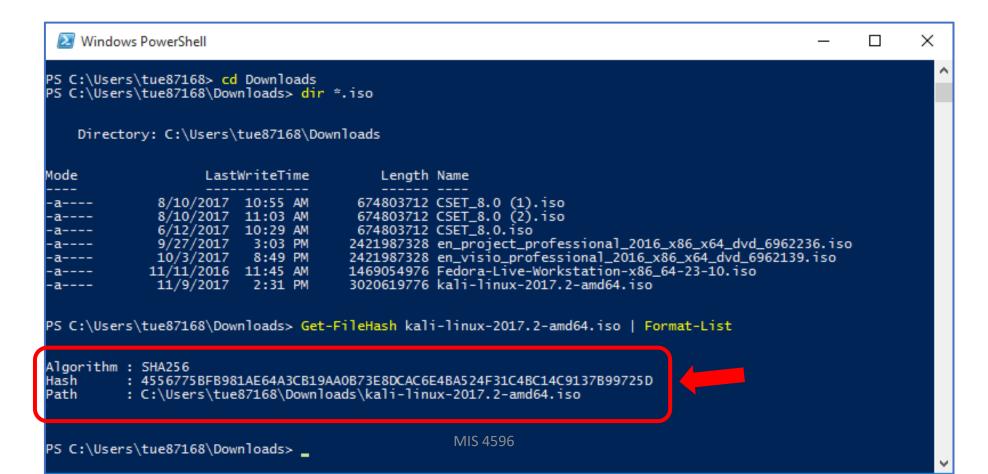

One-way hash example...

Testing the integrity of a file (e.g. program) downloaded from the internet...

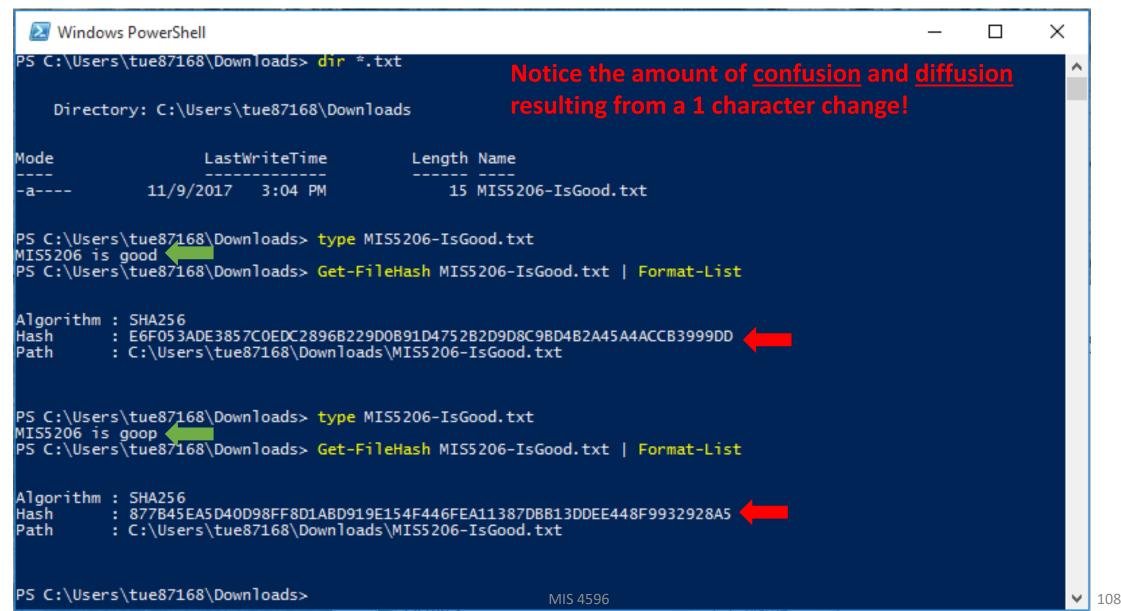

One-way hash example...

Image Name	Download	Size	Version	sha256sum
Kali 64 bit	HTTP Torrent	2.8G	2017.2	4556775bfb981ae64a3cb19aa0b73e8dcac6e4ba524f31c4bc14c9137b99725d

One-way hash example...

Cryptanalysis Attack

Collisions

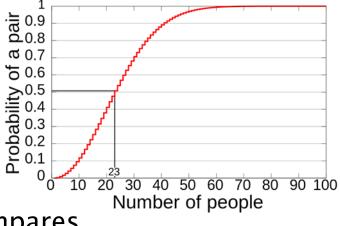

- Two different messages with the same hash value
- Based on the "birthday paradox"
- Hash algorithms should be resistant to this attack

The birthday paradox, also known as the birthday problem, states that in a random group of 23 people, there is about a 50 percent chance that two people have the same birthday.

109 MIS 4596

Is the Birthday Attack Real?

• There are multiple reasons why this seems like a paradox

One is that when in a room with 22 other people, if a person compares
his or her birthday with the birthdays of the other people it would make
for only 22 comparisons—only 22 chances for people to share the same
birthday.

When all 23 birthdays are compared against each other, it makes for much more than 22 comparisons. How much more? Well, the first person has 22 comparisons to make, but the second person was already compared to the first person, so there are only 21 comparisons to make. The third person then has 20 comparisons, the fourth person has 19 and so on. If you add up all possible comparisons (22 + 21 + 20 + 19 + ... +1) the sum is 253 comparisons, or combinations.

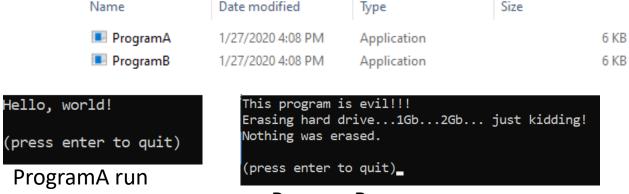

Consequently, each group of 23 people involves 253 comparisons, or 253 chances for matching birthdays.

MIS 4596

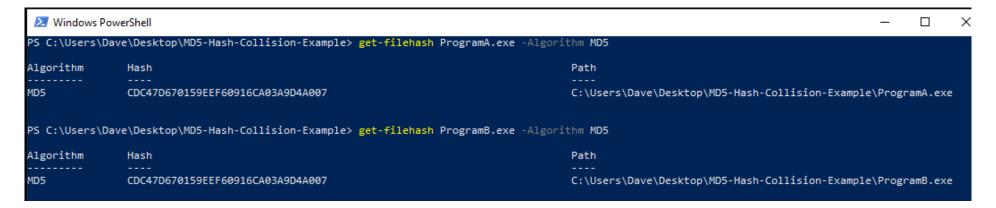

MD5 (Message Digest 5)

- A 128-bit hash algorithm, still in common use
- Has been broken
- 128-bit hash, but only need $2^{128/2} = 2^{64}$ to find a collision
- Not strong enough for modern computers

Example of an MD5 hash collision:

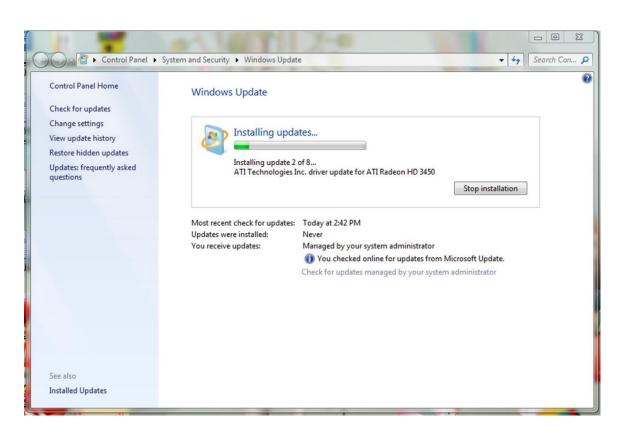

ProgramB run

In 2012 malware Flame used a MD5 hash collision to hijack Microsoft Windows Update and spread itself across networks

- Flame collected audio, keystrokes, screenshots which it sent to a malicious server
- Found a collision within a single millisecond
- Cost ~\$200k computing time just for 1ms
- Attributed to advanced persistent threat group <u>Equation Group</u>
- Used in espionage attacks on countries

SHA -1 (Security Hash Algorithm 1)

- A 160-bit hash algorithm, still in common use
- Has been broken
- 160-bit hash, but only need $2^{160/2} = 2^{80}$ to find a collision
- No longer strong enough for modern computers

SHA-2 uses 224, **256**, 384, and 512-bit hashes

- But... it is built using the design of SHA-1, and prone to the same weaknesses
- It's believed to be a matter of time before SHA-2 is also exploited

SHA-3 was recently ratified by NIST, the U.S. National Institute of Standards and Technology

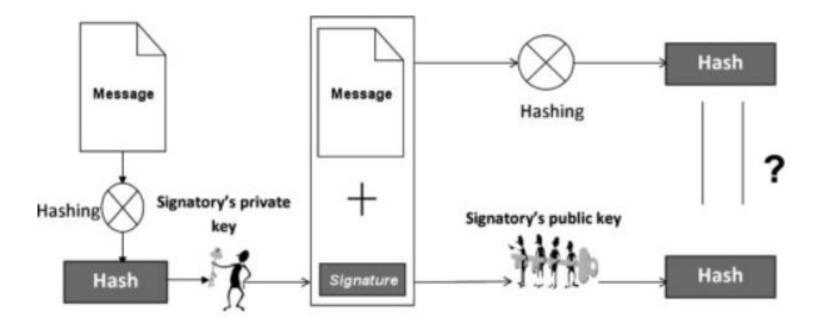

• It was the result of a six-year hashing competition. Also uses 224-, 256-, 384-, 512-bit hashes

Why does this matter for businesses?

Business needs a reliable way to prove integrity of data, files, programs, that can be trusted

Digital Signature

The act of signing means encrypting the message's hash value with the private key

MIS 4596 114

Services of cryptosystems

- ✓ Confidentiality Renders information unintelligible except by authorized entities
- ✓ **Authentication** Verifies the identity of the user or system that created, requested or provided the information
- ✓ Nonrepudiation Ensure the sender cannot deny sending the information
- ✓ **Integrity** Data has not been altered in an unauthorized manner since it was created, transmitted, or stored

Summary: Symmetric Algorithms

Name	Key Length (bits)	Block Size (bits)	Notes
DES	56 (56 + 8 parity)	64	Replaced by 3DES
3DES	56, 112, or 168 (+ 8, 16, 24 parity)	64	Replaced by AES
Blowfish	32 to 448	64	Replaced by Twofish
TwoFish	128, 192, or 256	128	Slower than AES.
AES (Rijandel)	128, 192, or 256	128	FIPS 197
RC4	8 to 2048-bit key (usually 40 to 256)	Stream	No longer in use
RC5	Variable (up to 2048)	32, 64, or 128	Very Strong
RC6	128, 192, and 256 bits up to 2040- bits	128	Based on RC5. (RSA)

Summary: Hashing Algorithms (Integrity)

	Hash Size (bits)	Block Size (bits)	Rounds	Strength	
MD5	128	512	64	Weak – Password Files	
SHA-0	160	512	80	Weak	
SHA-1	160	512	80	Generally not recommended for Federal Systems – Refer to NIST SP800-131A for allowable uses.	
SHA-2 (224 or 256)	224 or 256	512	64	Acceptable, 256 recommended	
SHA-2 (384 or 512)	384 or 512	1024	80	All of the following are acceptable. Refer to NIST SP800-57 Part 1	
SHA-512/224	224	1024	80		
SHA-512/256	256	1024	80		
SHA3-224	224	1600	1152		
SHA3-256	256	1600	1088		
SHA3-384	384	1600	832		
SHA3-512	512	1600	576		

https://csrc.nist.gov/Projects/Hash-Functions/NIST-Policy-on-Hash-Functions

Summary: Asymmetric Algorithms (primarily used for key transport/exchange)

- RSA is the Public Key Cryptography Standard #1 (PKCS)
- Diffie-Hellman replaced by El Gamal
- El Gamal
- Elliptic Curve Cryptography
 - ECDH
 - ECDSA

Agenda

Quiz

Which control is the BEST way to ensure that the data in a file have not been changed during transmission?

- a) Reasonableness check
- b) Parity bits
- c) Hash values
- d) Check digits

The PRIMARY reason for using digital signatures is to ensure data:

- a) confidentiality
- b) integrity
- c) availability
- d) Timeliness

Which of the following provides the GREATEST assurance for database password encryption?

- a) Secure hash algorithm-256 (SHA-256)
- b) Advanced encryption standard (AES)
- c) Secure Shell (SSH)
- d) Triple data encryption standard (3DES)

Email message authenticity and confidentiality is BEST achieved by signing the message using the:

- a) Sender's private key and encrypting the message using the receiver's public key
- b) Sender's public key and encrypting the message using the receiver's private key
- c) Receiver's private key and encrypting the message using the sender's public key
- d) Receiver's public key and encrypting the message using the sender's private key
